# HOW MANY PRIMES CAN DIVIDE THE VALUES OF A POLYNOMIAL? 

FLORIAN LUCA AND PAUL POLLACK<br>For Andrzej Schinzel on his seventy-fifth birthday

#### Abstract

Let $F(T) \in \mathbb{Z}[T]$ be a nonconstant polynomial. We prove a result concerning the maximal order of $\Omega(F(n))$, where $\Omega(\cdot)$ denotes the total number of prime factors (counting multiplicity). In the case when $F$ has only simple roots, the result asserts that

$$
\limsup _{n \rightarrow \infty} \frac{\Omega(F(n))}{\log n}=\frac{1}{\log \ell},
$$

where $\ell$ is the least prime for which $F$ has a zero in the $\ell$-adic integers $\mathbb{Z}_{\ell}$. This extends investigations of Erdős and Nicolas, who treated the case $F(T)=T(T+1)$.

## 1. Introduction

Let $\Omega(n):=\sum_{p^{k} \mid n} 1$ denote the number of (positive) prime factors of $n$, counted with multiplicity. The study of statistical properties of $\Omega(n)$ was a major impetus for the development of probabilistic number theory in the first half of the twentieth century. It is a simple consequence of elementary prime number theory that $\Omega(n)$ behaves like $\log \log n$ on average. Hardy and Ramanujan [HR17] showed that this average behavior is typical by demonstrating that $\Omega(n) \sim \log \log n$ as $n \rightarrow \infty$ along a set of asymptotic density 1. This result was refined in celebrated work of Erdős and Kac [EK40], who proved that $\Omega(n)$ possesses a Gaussian distribution with mean and variance $\log \log n$. In contrast with the depth of these authors' work, the minimal and maximal orders of $\Omega(n)$ are trivial to determine: $\Omega(n)=1$ for prime $n$, while $\Omega(n)=\frac{\log n}{\log 2}$ when $n$ is a power of 2 .

Let $F(T) \in \mathbb{Z}[T]$ be a fixed polynomial. One can ask for the average, normal, minimal, and maximal orders of $\Omega(F(n))$. The first two questions have been satisfactorily resolved (see, e.g., [Hal56] for an analogue of the Erdős-Kac theorem in this context). The third question is in general very difficult; to take a famous example, we expect that if $F(T)=T(T+2)$, then $\Omega(F(n))=2$ infinitely often, but we are still far from proving this. Probably the following is true:

[^0]Hypothesis $\mathbf{H}^{\prime}$. Let $F(T)$ be a nonzero polynomial with integer coefficients. Let $D:=\operatorname{gcd}_{n \in \mathbb{Z}}\{F(n)\}$ be the greatest fixed divisor of $F$. Then

$$
\liminf _{n \rightarrow \infty} \Omega(F(n))=r+\Omega(D)
$$

where $r$ is the number of monic irreducible factors of $F$ in $\mathbb{Q}[T]$, counted with multiplicity.

We remark that it is easy to compute $D=D(F)$ for a given $F$. Indeed, setting $d:=\operatorname{deg} F$, a theorem of Hensel [Hen96] asserts that

$$
D(F)=\operatorname{gcd}(F(0), F(1), \ldots, F(d))
$$

Moreover, Pólya [Pol15] has shown (cf. [Bha00]) that if the coefficients of $F$ do not all share a common factor $>1$, then $D(F) \mid d!$.

We show in $\S 2$ that Hypothesis $\mathrm{H}^{\prime}$ is equivalent to Schinzel's well-known Hypothesis H [SS58] concerning simultaneous prime values of polynomials. This equivalence, and its proof, are similar in flavor to Schinzel's own argument [Sch62] that his Hypothesis H implies a conjecture of Bunyakovsky.

The primary purpose of this note is to give a satisfactory answer to the remaining, fourth question: What is the maximal order of $\Omega(F(n))$ ? Erdős and Nicolas [EN80] considered this problem when $F(T)=T(T+1)$, so that $\Omega(F(n))=\Omega(n)+\Omega(n+1)$. Trivially, $\Omega(F(n)) \leq 2 \frac{\log (n+1)}{\log 2}$. But these authors showed [EN80, Théorème 3] that in fact,

$$
\Omega(n(n+1)) \leq(1+o(1)) \frac{\log n}{\log 2} \quad(\text { as } n \rightarrow \infty)
$$

We show that $\Omega(F(n))$ always has maximal order $C \log n$ for some positive constant $C$. More precisely, factor $F$ as

$$
\begin{equation*}
F(T)= \pm \operatorname{Cont}(F) \prod_{i=1}^{k} F_{i}(T)^{e_{i}} \tag{1.1}
\end{equation*}
$$

where $\operatorname{Cont}(F)$ is the content of $F$ (the greatest common divisor of its coefficients) and the $F_{i}$ are distinct irreducible elements of $\mathbb{Z}[T]$, each with positive leading term. For each $1 \leq i \leq k$, we let $\ell_{i}$ denote the least prime $\ell$ for which $F_{i}$ has a root in the $\ell$-adic integers $\mathbb{Z}_{\ell}$ (equivalently, for which $F_{i}$ has a zero modulo every power of $\ell$ ). To see that $\ell_{i}$ is well-defined, first note that a straightforward variant of Euclid's proof of the infinitude of primes shows that $F_{i}$ has a root modulo $\ell$ for infinitely many primes $\ell$ (see, for example, [Sch12, pp. 40-41]). For each such $\ell$ not dividing the resultant of $F_{i}$ and $F_{i}^{\prime}$, one sees from Hensel's lemma that $F$ has a root in $\mathbb{Z}_{\ell}$. We can now state our main result.

Theorem 1. Let $F(T) \in \mathbb{Z}[T]$ be a nonconstant polynomial with integer coefficients. Suppose that $F$ is written in the form (1.1). For each $1 \leq i \leq k$, define $\ell_{i}$ as above. Then

$$
\limsup _{n \rightarrow \infty} \frac{\Omega(F(n))}{\log n}=C(F), \quad \text { where } \quad C(F):=\max _{1 \leq i \leq k} \frac{e_{i}}{\log \ell_{i}} .
$$

In particular, if $F$ has only simple roots, then $C(F)=1 / \log \ell$, where $\ell$ is the least prime for which $F$ has a zero in $\mathbb{Z}_{\ell}$.

Our proof is similar in spirit to that of Erdős and Nicolas, but replaces the use of Ridout's version of Roth's theorem with an application of the subspace theorem.

The questions we have raised make sense also for $\omega(F(n))$, where $\omega$ counts the number of distinct prime factors. However, as observed already by Erdős and Nicolas, here it seems very difficult to prove any nontrivial results about the maximal order. To illustrate the difficulties, call the natural number $n$ special if $n(n+1)$ is the product of the first $k$ primes for some $k$; e.g., $n=714$ is special, with $k=7$. Improving the trivial bound

$$
\limsup _{n \rightarrow \infty} \frac{\omega(n(n+1))}{\log n / \log \log n} \leq 2
$$

entails showing that there are only finitely many special $n$. This conjecture, first proposed by Nelson, Penney, and Pomerance [NPP74], seems unattackable at present. It may be mentioned that in a 2009 preprint, A. Dąbrowski conjectured that there are precisely 28 solutions to the equation

$$
\begin{equation*}
N^{2}-1=p_{1}^{a_{1}} \cdots p_{k}^{a_{k}} \tag{1.2}
\end{equation*}
$$

where $N$ and the $a_{i}$ are positive integers, and $p_{i}$ denotes the $i$ th prime. Note that if $n$ is special, then $N=2 n+1$ gives a solution to (1.2). The results of [LN11] imply the truth of Dąbrowski's conjecture for all $k \leq 25$.

Notation. Most of our notation is standard or will be explained when needed, so we make only a few brief remarks: We let $|\cdot|$ (without a subscript) denote the usual absolute value on $\mathbb{C}$. For a prime $p$ and a nonzero rational number $x$, we write $\operatorname{ord}_{p}(x)$ for the exponent of $p$ in the prime factorization of $x$. We say that a number $n$ is $y$-smooth if each prime factor of $n$ is bounded by $y$, and we define the $y$-smooth part of $n$ as its largest $y$-smooth divisor.
2. Minimal order: The equivalence of Hypotheses H and H'

We begin by recalling the statement of Schinzel's Hypothesis H [SS58]:

Hypothesis H. Suppose that $G_{1}(T), \ldots, G_{k}(T) \in \mathbb{Z}[T]$ are irreducible over $\mathbb{Q}$, each with positive leading coefficient. Put $G:=\prod_{i=1}^{k} G_{i}$. Suppose that $G$ has no fixed prime divisor: for every prime $p$, there is an integer $m_{p}$ for which $p \nmid G\left(m_{p}\right)$. Then there are infinitely many natural numbers $n$ for which each $G_{i}(n)$ is prime.

It is clear that Hypothesis $\mathrm{H}^{\prime}$ implies H : We need only apply $\mathrm{H}^{\prime}$ with $F=\prod_{i=1}^{r} G_{i}$ (assuming, as we may, that the $G_{i}$ are distinct). So we may focus our energies on showing that H implies $\mathrm{H}^{\prime}$.

Let $F(T) \in \mathbb{Z}[T]$ be a nonzero polynomial for which we wish to establish the conclusion of Hypothesis $\mathrm{H}^{\prime}$. We can assume that $F$ is nonconstant and that $\operatorname{Cont}(F)=1$. Hence, we may write $F=\prod_{i=1}^{k} F_{i}(T)^{e_{i}}$, where each $F_{i}(T)$ is nonconstant, irreducible over $\mathbb{Z}$, and possesses a positive leading coefficient. Let $D=\operatorname{gcd}_{n \in \mathbb{Z}}\{F(n)\}$; we must prove that

$$
\liminf _{n \rightarrow \infty} \Omega(F(n))=\Omega(D)+r, \quad \text { where } \quad r:=\sum_{i=1}^{k} e_{i}
$$

It is easy to prove that $\Omega(F(n)) \geq \Omega(D)+r$ for all large $n$. Indeed, since $D \mid F(n)=\prod_{i=1}^{k} F_{i}(n)^{e_{i}}$, there is a factorization $D=\prod_{i=1}^{k} D_{i}$ where each $D_{i} \mid F_{i}(n)^{e_{i}}$. Then with $D_{i}^{\prime}:=\prod_{p} p^{\left\lceil\left(\operatorname{ord}_{p} D_{i}\right) / e_{i}\right\rceil}$, we have $D_{i}^{\prime} \mid F_{i}(n)$ for all $1 \leq i \leq n$, and so

$$
F(n)=\left(\prod_{i=1}^{k} D_{i}^{\prime e_{i}}\right)\left(\prod_{i=1}^{k}\left(F_{i}(n) / D_{i}^{\prime}\right)^{e_{i}}\right)
$$

The first product contributes at least $\Omega(D)$ prime factors, since $D=\prod D_{i} \mid$ $\prod D_{i}^{\prime e_{i}}$, and the second product contributes at least $\sum_{i=1}^{k} e_{i}=r$ primes (for large $n$ ). This gives the desired lower bound on $\Omega(F(n))$.

Turning to the upper bound, let $\mathcal{S}$ be the set of primes $p$ for which either $p \mid D$ or $p \leq \operatorname{deg} F$. For each $p \in \mathcal{S}$, choose an integer $n_{p}$ so that $p^{1+\operatorname{ord}_{p}(D)} \nmid F\left(n_{p}\right)$. Choose $n_{0}$ to satisfy the simultaneous congruences

$$
n_{0} \equiv n_{p} \bmod p^{1+\operatorname{ord}_{p}(D)} \quad \text { for all } p \in \mathcal{S}
$$

With $M:=\prod_{p \in \mathcal{S}} p^{1+\operatorname{ord}_{p}(D)}$, put $\tilde{F}_{i}(T)=F_{i}\left(M T+n_{0}\right)$, and set $\tilde{F}(T)=$ $F\left(M T+n_{0}\right)$, so that $\tilde{F}(T)=\prod_{i=1}^{k} \tilde{F}_{i}(T)^{e_{i}}$. Since $D \mid M$ and $D \mid F\left(n_{0}\right)$, it is clear that $\tilde{F}(T) / D \in \mathbb{Z}[T]$. Moreover, $\tilde{F}(T) / D$ has no fixed prime divisor: Indeed, $\operatorname{gcd}(\tilde{F}(0) / D, M)=\operatorname{gcd}\left(F\left(n_{0}\right) / D, M\right)=1$ by construction, so that no prime in $\mathcal{S}$ is a fixed divisor of $\tilde{F}(T)$. Moreover, if $p \notin \mathcal{S}$, then the reduction of $\tilde{F}(T)$ modulo $p$ is nonzero and has degree $\leq \operatorname{deg} F<p$, so that again $p$ is not a fixed divisor of $\tilde{F}(T) / D$.

Since $\tilde{F}(T) / D$ has no fixed prime divisor, we have in particular that

$$
\begin{equation*}
D=\operatorname{Cont}(\tilde{F})=\prod_{i=1}^{k} \operatorname{Cont}\left(\tilde{F}_{i}\right)^{e_{i}} \tag{2.1}
\end{equation*}
$$

Let $G_{i}(T):=\tilde{F}_{i}(T) / \operatorname{Cont}\left(\tilde{F}_{i}\right)$. Since each $F_{i}$ is irreducible over $\mathbb{Q}$, so is each $G_{i}$. In $\mathbb{Z}[T]$, we have (referring back to (2.1))

$$
G(T):=\prod_{i=1}^{k} G_{i}(T) \mid \prod_{i=1}^{k} G_{i}(T)^{e_{i}}=\tilde{F}(T) / D
$$

as $\tilde{F}(T) / D$ has no fixed prime divisor, neither does $G(T)$. So by Hypothesis H , there are infinitely many $n$ for which each $G_{i}(n)$ is prime. For any such $n$, it is clear that

$$
F\left(M n+n_{0}\right)=\tilde{F}(n)=D \prod_{i=1}^{k} G_{i}(n)^{e_{i}}
$$

has precisely $\Omega(D)+\sum_{i} e_{i}=\Omega(D)+r$ prime factors, as desired.

## 3. Maximal order

3.1. The lower bound. It is simple to prove that $\Omega(F(n))$ is occasionally at least as large as predicted here: Fix $1 \leq i \leq r$ so that the ratio $e_{i} / \log \ell_{i}$ is maximal. Write $e=e_{i}$ and $\ell=\ell_{i}$ (to ease notation). For each natural number $j$, choose $n_{j} \in\left[\ell^{j}, 2 \ell^{j}\right)$ so that $F_{i}\left(n_{j}\right) \equiv 0\left(\bmod \ell^{j}\right)$. Then the $n_{j}$ tend to infinity and

$$
\Omega\left(F\left(n_{j}\right)\right) \geq e \cdot \Omega\left(F_{i}\left(n_{j}\right)\right) \geq e \cdot j \geq e \frac{\log \left(n_{j} / 2\right)}{\log \ell}
$$

This shows that the limsup considered in Theorem 1 is at least as large as predicted.
3.2. The upper bound. To see that the limsup in Theorem 1 is no larger than predicted, we use a version of Schmidt's subspace theorem due to Schlickewei. First, some terminology. For a nonzero rational number $x$, its infinite valuation is $|x|_{\infty}=|x|$. Finite valuations correspond to prime numbers $p$, and for such a prime, the $p$-adic valuation of $x$ is taken to be $|x|_{p}=p^{-\operatorname{ord}_{p}(x)}$. Put $\mathcal{M}_{\mathbb{Q}}=\{p: p$ prime $\} \cup\{\infty\}$. Such valuations are sometimes called normalized since the product formula

$$
\prod_{v \in \mathcal{M}_{\mathbb{Q}}}|x|_{v}=1 \quad \text { holds for all } \quad x \in \mathbb{Q}^{*}
$$

Often one extends these valuations to all algebraic numbers. A canonical way to do this is the following. Let $\mathbb{K}$ be an algebraic number field of degree $d$ over $\mathbb{Q}$. The infinite valuations $v$ of $\mathbb{K}$ are in correspondence with the
embeddings $\sigma: \mathbb{K} \hookrightarrow \mathbb{C}$. If $\sigma$ is real and $x \in \mathbb{K}$, then $|x|_{v}=|\sigma(x)|^{1 / d}$, whereas if $\sigma$ is complex non-real then $|x|_{v}=|\sigma(x)|^{2 / d}$. Finite valuations of $\mathbb{K}$ are in correspondence with prime ideals $\pi$ in $\mathcal{O}_{\mathbb{K}}$. More precisely, say $\pi$ is a prime ideal in $\mathbb{K}$ of norm $N_{\mathbb{K} / \mathbb{Q}}(\pi)=p^{f}$. Then $|x|_{v}=p^{-c_{v} \operatorname{ord}_{\pi}(x)}$, where $c_{v}=f / d$, and $\operatorname{ord}_{\pi}(x)$ is the exponent at which the prime ideal $\pi$ appears in the factorization of the fractional ideal $x \mathcal{O}_{\mathbb{K}}$ generated by $x$ inside $\mathbb{K}$. Put $\mathcal{M}_{\mathbb{K}}$ for the set of all valuations of $\mathbb{K}$. Then one checks easily that the formula

$$
\prod_{v \in \mathcal{M}_{\mathbb{K}}}|x|_{v}=1 \quad \text { holds for all } \quad x \in \mathbb{K}^{*}
$$

Let $m \geq 2$ be given, and let $\mathcal{S}$ be a finite subset of $\mathcal{M}_{\mathbb{K}}$ containing all the infinite valuations. Assume that for each $v \in \mathcal{S}$ we are given a system of $m$ linearly independent linear forms $L_{v, i}(\mathbf{x})$ in $\mathbf{x}=\left(x_{1}, \ldots, x_{m}\right)$ with coefficients in $\mathbb{K}$. Using $x_{i}^{(j)}(1 \leq j \leq d)$ for the conjugates of $x_{i}$, put

$$
\|\mathbf{x}\|:=\max _{\substack{1 \leq i \leq m \\ 1 \leq j \leq d}}\left|x_{i}^{(j)}\right|
$$

Then the $\mathfrak{p}$-adic subspace theorem of Schlickewei [Sch77] (in the formulation of [Sch91, Theorem 1D, p. 177]) says the following:

Theorem A. For each $\varepsilon>0$, the solutions $\mathbf{x} \in \mathcal{O}_{\mathbb{K}}^{m}$ of the inequality

$$
\prod_{v \in \mathcal{S}} \prod_{i=1}^{m}\left|L_{v, i}(\mathbf{x})\right|_{v}<\|x\|^{-\varepsilon}
$$

lie in finitely many proper subspaces of $\mathbb{K}^{m}$.
The proof of the upper-bound assertion of Theorem 1 is based on the following lemma:

Lemma 1. Let $F(T) \in \mathbb{Z}[T]$ be a polynomial of degree $d \geq 1$ with only simple roots. Fix $Z>0$. For each natural number $n$ for which $F(n) \neq 0$, write $F(n)=U V$, where $U$ is the $Z$-smooth part of $F$. Given $\epsilon>0$, we have $U>n^{1+\epsilon}$ for only finitely many natural numbers $n$.

Proof of Lemma 1. We can assume that $d \geq 2$, otherwise there is nothing to prove. We can also assume that $F$ is monic. To see this, write $c_{d}$ for the leading coefficient of $F$. Replacing $F$ with $-F$ if necessary, we can assume that $c_{d}>0$. Then $c_{d}^{d-1} F(T)=G\left(c_{d} T\right)$ for some monic $G$ of the same degree as $F$ (still with only simple roots), and the lemma holds for $F$ provided that it holds for $G$.

Let $\mathbb{K}$ be the splitting field of $F$ and write

$$
F(T)=\left(T-\theta_{1}\right)\left(T-\theta_{2}\right) \cdots\left(T-\theta_{d}\right)
$$

Let $\mathcal{N}$ be the set of $n$ such that $F(n)=U V$, with $U>n^{1+\varepsilon}$ and $Z$-smooth. Since $F(T)$ is monic, the numbers $\theta_{1}, \ldots, \theta_{d}$ are all in $\mathcal{O}_{\mathbb{K}}$. Put $m=2$, $\mathbf{x}=\left(x_{1}, x_{2}\right)$. We shall take $x_{1}=n-\theta_{1}$ and $x_{2}=n-\theta_{2}$. We take $\mathcal{S}$ to be the finite subset of $\mathcal{M}_{\mathbb{K}}$ consisting of the following valuations:
(i) all the infinite valuations of $\mathbb{K}$;
(ii) all the finite valuations of $\mathbb{K}$ sitting above some prime number $p \leq Z$.

To define the forms $L_{v, i}(\mathbf{x})$ for $v \in \mathcal{S}$ and $i=1,2$, it is helpful to introduce the notion of type. Let $\mathcal{P}$ be the set of finite valuations of $\mathcal{S}$. To each $n \in \mathcal{N}$ we associate a type function $f: \mathcal{P} \rightarrow\{1,2, \ldots, d\}$, as follows: Let $\pi \in \mathcal{P}$. For each $1 \leq i \leq d$, write

$$
\left(n-\theta_{i}\right) \mathcal{O}_{\mathbb{K}}=\pi^{e_{i}} I_{i, \pi},
$$

where $I_{i, \pi}$ is an ideal of $\mathcal{O}_{\mathbb{K}}$ coprime to $\pi$ and $e_{i}$ is a nonnegative integer. We define $f(\pi) \in\{1,2, \ldots, d\}$ as that index $i$ for which $e_{i}$ is as large as possible, choosing arbitrarily among the possibilities if more than one such $i$ exists. The number of possible types is finite. So to show that $\mathcal{N}$ is finite, it suffices to show that there are only finitely many $n$ having a fixed type $f$.

We are now ready to define the forms $L_{v, i}(\mathbf{x})$. If $v$ is infinite, we take $L_{v, 1}(\mathbf{x})=x_{1}$ and $L_{v, 2}(\mathbf{x})=x_{1}-x_{2}$. It is clear that they are independent. Say that $\theta_{1}$ has degree $d_{1} \mid d$, with minimal polynomial $F_{1} \mid F$. For large $n$,

$$
\begin{align*}
\prod_{v \text { infinite }} L_{v, i}(\mathbf{x}) & =\prod_{v \text { infinite }}\left|n-\theta_{1}\right|_{v} \prod_{v \text { infinite }}\left|\theta_{1}-\theta_{2}\right| \\
& \asymp N_{\mathbb{K} / \mathbb{Q}}\left(n-\theta_{1}\right)^{1 / d}=F_{1}(n)^{1 / d_{1}} \asymp n . \tag{3.1}
\end{align*}
$$

(The implied constants may depend on $F$.) In order to proceed to the finite valuations, observe first that for $i=3, \ldots, d$, we have $n-\theta_{i}=c_{i} x_{1}+d_{i} x_{2}$, where $\left(c_{i}, d_{i}\right)$ is the unique solution of the system $c_{i}+d_{i}=1$ and $c_{i} \theta_{1}+d_{i} \theta_{2}=$ $\theta_{i}$. Observe that $d_{i} \neq 0$, as otherwise $c_{i}=1$ and $\theta_{1}=c_{i} \theta_{1}=\theta_{i}$. If now $v \in \mathcal{P}$ corresponds to a prime ideal $\pi$, we then take $L_{v, 1}(\mathbf{x})=x_{1}$ and $L_{v, 2}(\mathbf{x})=x_{2}$ if $f(\pi) \in\{1,2\}$, and $L_{v, 1}(\mathbf{x})=x_{1}$ and $L_{v, 2}=c_{i} x_{1}+d_{i} x_{2}$ if $f(\pi)=i \geq 3$. In all cases, $L_{v, 1}(\mathbf{x})$ and $L_{v, 2}(\mathbf{x})$ are independent. It remains to compute $\left|L_{v, i}(\mathbf{x})\right|_{v}$ for $i=1,2$. Continuing to denote $f(\pi)$ by $i$, note that if $j \neq i$, then $e_{j} \leq e_{i}$, so that $\pi^{e_{j}}$ divides $n-\theta_{j}$ and $n-\theta_{i}$. Thus, it also divides $\theta_{j}-\theta_{i}$. Hence,

$$
\pi^{\sum_{j \neq i} e_{j}}\left|\prod_{j \neq i}\left(\theta_{j}-\theta_{i}\right)\right| \Delta(F)
$$

where $\Delta(F)$ is the discriminant of $F$. This shows immediately that

$$
\left|L_{v, 1}(\mathbf{x})\right|_{v}\left|L_{v, 2}(\mathbf{x})\right|_{v} \leq\left|n-\theta_{i}\right|_{v} \leq \frac{|f(n)|_{v}}{|\Delta(F)|_{v}}
$$

Hence,

$$
\begin{equation*}
\prod_{\substack{v \in \mathcal{S} \\ v \text { finite }}}\left|L_{v, 1}(\mathbf{x})\right|_{v}\left|L_{v, 2}(\mathbf{x})\right|_{v} \leq \prod_{\substack{v \in \mathcal{S} \\ v \text { finite }}} \frac{|f(n)|_{v}}{|\Delta(F)|_{v}} \leq \frac{|\Delta(F)|}{U} \ll \frac{1}{U} \tag{3.2}
\end{equation*}
$$

Thus, putting together (3.1) and (3.2), we have

$$
\prod_{v \in \mathcal{S}} \prod_{i=1}^{2}\left|L_{v, i}(\mathbf{x})\right|_{v} \ll \frac{n}{U} \ll \frac{1}{n^{\varepsilon}} \ll\|x\|^{-\varepsilon} .
$$

By Theorem A, all solutions $\mathbf{x}$ are contained in finitely many subspaces of $\mathbb{K}^{2}$. In other words, there is a positive integer $K$ and $K$ pairs $\left(C_{1}, D_{2}\right)$, $\ldots,\left(C_{K}, D_{K}\right)$ of numbers in $\mathbb{K}$, not both zero, such that each such solution $\mathbf{x}$ satisfies $C_{i} x_{1}+D_{i} x_{2}=0$ for some $1 \leq i \leq K$. Take an $i$ with $1 \leq i \leq K$. If $C_{i}=0$, then $D_{i} \neq 0$; thus, $x_{2}=0$ and $n=\theta_{2}$. Similarly, if $D_{i}=0$, then $x_{1}=0$ and $n=\theta_{1}$. If neither $C_{i}$ nor $D_{i}$ vanishes, then $\left(n-\theta_{1}\right) /\left(n-\theta_{2}\right)=$ $x_{1} / x_{2}=-D_{i} / C_{i}$, which uniquely determines $n$. So there are only finitely many possibilities for $n$, as desired.

Completion of the proof of Theorem 1. It remains only to prove the upper bound for the limsup. For an interval $I$, let us write $\Omega_{I}(n):=\sum_{p^{k} \mid n, p \in I} 1$ for the number of prime power divisors $p^{k}$ of $n$ with $p \in I$.

Fix a large real number $Z$. Write $F$ in the form (1.1). By the choice of $\ell_{i}$, each prime $<\ell_{i}$ divides $F_{i}(n)$ to a bounded power. Hence, for large $n$,

$$
\begin{align*}
& \Omega(F(n))=\Omega(\operatorname{Cont}(F))+  \tag{3.3}\\
& \begin{aligned}
\sum_{i=1}^{k} e_{i}\left(\Omega_{\left[1, e_{i}\right)}\left(F_{i}(n)\right)\right. & \left.+\Omega_{\left[\ell_{i}, Z\right]}\left(F_{i}(n)\right)+\Omega_{(Z, \infty)}\left(F_{i}(n)\right)\right) \\
& =O(\log n / \log Z)+\sum_{i=1}^{k} e_{i} \cdot \Omega_{\left[\ell_{i}, Z\right]}\left(F_{i}(n)\right),
\end{aligned}
\end{align*}
$$

where for an interval $I$ we use $\Omega_{I}(m)$ for the number of prime factors of $m$ in $I$, multiple factors counted multiply. (As before we suppress the dependence of the implied constants on $F$.) Let $U_{i}$ denote the $Z$-smooth part of $F_{i}(n)$, so that

$$
\begin{equation*}
\Omega_{\left[\ell_{i}, Z\right]}\left(F_{i}(n)\right) \leq \frac{\log U_{i}}{\log \ell_{i}} \tag{3.4}
\end{equation*}
$$

We now apply Lemma 1 with $G(T):=\prod_{i=1}^{k} F_{i}(T)$. Writing $G(n)=U V$, where $U$ is the $Z$-smooth part of $G(n)$, we find that $U \leq n^{1+o(1)}$ as $n \rightarrow \infty$, and so

$$
\begin{equation*}
\sum_{i=1}^{k} \frac{\log U_{i}}{\log n} \leq 1+o(1) \tag{3.5}
\end{equation*}
$$

From (3.3), (3.4), (3.5), and the definition of $C(F)$ given in the theorem statement,

$$
\begin{aligned}
\Omega(F(n)) & \leq \log n \sum_{i=1}^{k} \frac{\log U_{i}}{\log n} \frac{e_{i}}{\log \ell_{i}}+O(\log n / \log Z) \\
& \leq(C(F)+o(1)) \log n+O(\log n / \log Z) .
\end{aligned}
$$

Dividing by $\log n$ and letting $n \rightarrow \infty$ gives that $\lim \sup \Omega(F(n)) / \log n \leq$ $C(F)+O(1 / \log Z)$. Since $Z$ can be taken arbitrarily large, the result follows.

## Acknowledgements

The authors thank Carl Pomerance, Enrique Treviño, and the referee for suggestions which improved the quality of the manuscript. This research was conducted while P. P. was supported by NSF award DMS-0802970.
